Abstract: Foreign bodies in ENT (Ear, Nose, Throat) often cause emergencies following their appearance, their location and can be life-threatening. The aim of this work was to study the epidemiological and clinical profile of foreign bodies in ENT in a peripheral health center of Bamako. This was a cross-sectional study carried out in the ENT department of the Reference Health Center of Commune V of Bamako from January 2018 to December 2018. In our current study, the frequency of foreign bodies in ENT was 1.47% (68 cases) detected from 4630 medical consultations. The male / female ratio was 1.12, ie 36 men and 32 women. The 0 to 5 age group represented 42.6%. The average age was 15 years with extremes of 10 months and 76 years. We identified 58.9% of foreign bodies from ear, 32.4% from the nasal cavity; those of the bronchi, esophagus and pharynx each accounted for 2.9%. Cotton represented 19.1%, pebbles and food foreign bodies (13.2% each); and a button cell battery case. Foreign bodies are most often seen in children in ENT. Their natures are diverse. It can be an emergency. Complications can be fatal. Prevention intervention must be taken. The adequacy of the technical platform taking care that important ENT aspect is essential.

Keywords: Foreign Body, Emergency, Child, ENT

1. Introduction

Foreign bodies are common in ear, nose and throat (ENT) consultations [1, 2]. They often cause health emergencies by their appearance (sharp, pointed), their location (nasal cavity, larynx) or their nature (button cell battery) and can quickly be life threatening. Neglected or old foreign bodies undetected can cause complications (traumatic laryngitis, suppurative mediastinitis, dilation of the bronchi) [1, 3]. Publications on this subject are frequent. However, they are quite often related to precise anatomical sites of the ENT

sphere (nasal foreign body, laryngotracheo-bronchial foreign body, foreign body of the esophagus of adults, foreign body of the aero-digestive tract of the child) [1, 3-6]. To ensure better care and prevention, the analysis of global local epidemiological data is necessary for health areas. The Reference Health Center of commune V is by its geographical location at the forefront of a large part of the Bamako population and its surroundings. This work was a descriptive study, in the form of part of the annual report of the otolaryngological consultation at the Reference Health Center of Commune V (CSRéf CV) in the district of Bamako

(Mali).

2. Objectives

- 1) Determine the frequency of foreign bodies in ENT
- 2) Study the socio-demographic characteristics of patients
- 3) To profile the different locations and the nature of the foreign bodies detected
- 4) Report the provided treatments

3. Materials and Method

The study was carried out in the ENT (Ear, Nose, Throat) and Head and Neck Surgery (HNS) department of the Reference Health Center of Commune V (CSRéf CV) of the District of Bamako in Mali. This was a cross-sectional study conducted over one year from January 2018 to December 2018 on patients that visited the ENT-HNS center for medical consultation. The inclusion criteria were any patient who had come for medical consultation and in whom a foreign body had been diagnosed. Patients who came for a medical consultation for another known ENT pathology, those treated by other services or already reaching the stage of complication after the extraction of foreign bodies and incomplete files were not included. The variables studied were: sex, age, location of foreign bodies, reason of the medical consultation, nature of the foreign bodies, treatment.

Table 1. Distribution of foreign bodies positive patients following their sex and the location of the foreign body.

Foreign body positive patients Sex	CEN	CEO	CEP	CEOE	CEB	Total
Male	07 (31.81%)	25 (62.5%)	01 (50%)	01 (50%)	02 (100%)	36 (52.94%)
Female	15 (68.18%)	15 (37.5%)	01 (50%)	01 (50%)	00 (0%)	32 (47.05%)
Total	22 (100%)	40 (100%)	02 (100%)	02 (100%)	02 (100%)	68 (100%)

CEN: Nasal foreign body. CEO: Foreign body in the ear. CEOE: Foreign body of the esophagus. CEB: Bronchial foreign body. CEP: Foreign body of the pharynx.

Foreign bodies from the nose were more common in girls (68.18%), while they were more common in the ear in boys, $p=0.0206$. For the other locations of foreign bodies, girls and boys were no significant difference ($p > 0.05$).

Table 2. Distribution of foreign bodies positive patients following their age depending on the nature of the foreign body.

foreign bodies positive patients age (year)	CEN	CEO	CEP	CEOE	CEB	Total
[0-5]	15 (68.18%)	10 (25%)	00 (0%)	02 (100%)	02 (100%)	29 (42.64%)
[5-10]	05 (22.72%)	08 (20%)	00 (0%)	00 (0%)	00 (0%)	13 (19.11%)
[10-15]	01 (4.54%)	06 (15%)	00 (0%)	00 (0%)	00 (0%)	07 (10.29%)
[15-20]	00 (0%)	01 (2.5%)	00 (0%)	00 (0%)	00 (0%)	01 (1.47%)
[20-25]	00 (0%)	02 (5%)	02 (100%)	00 (0%)	00 (0%)	04 (5.88%)
[25-30]	00 (0%)	01 (2.5%)	00 (0%)	00 (0%)	00 (0%)	01 (1.47%)
[30-35]	01 (4.54%)	02 (5%)	00 (0%)	00 (0%)	00 (0%)	03 (4.41%)
[35-40]	00 (0%)	05 (12.5%)	00 (0%)	00 (0%)	00 (0%)	05 (7.35%)
[40 et plus]	00 (0%)	05 (12.5%)	00 (0%)	00 (0%)	00 (0%)	05 (7.35%)
Total	22 (100%)	40 (100%)	02 (100%)	02 (100%)	02 (100%)	68 (100%)

CEN: Nasal foreign body. CEO: Foreign body in the ear. CEOE: Foreign body of the esophagus. CEB: Bronchial foreign body. CEP: Foreign body of the pharynx.

- 1) In children from 0-5 years old:
- 2) Foreign bodies were more common (68.18%) in the nose than in the ears (25%). $p=0.0009$.
- 3) They were more common in the esophagus (100%) than in the ear (25%). $p=0.0219$.
- 4) They were seen in the esophagus (100%) and in the bronchi (100%) while they were absent in the pharynx. $p=0.0455$.
- 5) In patients aged 20-25: All pharyngeal foreign bodies were present (100%) while there were no bronchial or

The information obtained was mentioned on an anonymous individual data collection sheet on which the variables to be studied appeared. Ethically, confidentiality and the informed consent of patients were respected. Statistical analysis was done by SPSS 22.0 software. The Chi2 statistical test was used.

4. Results

4.1. Frequency

With 68 recorded cases, the frequency of foreign bodies in ENT detected in this study was 1.47% (68 cases) with 36 men (52.9%) and 32 women (47.1%) all from 4630 medical consultations. The male / female ratio was 1.12 (Table 1).

4.2. Sociodemographic Aspects

The 0-to-5-years age group (Table 2) represented 42.6% of cases followed by the 5 to 10 year group 19.1% of cases. The average age was 15 years with extremes of 10 months and 76 years. Children under 15 were 72.05% of the series and the rest (27.95%) were over 15 years old. Preschool children accounted for 41.2%; pupils and students 32.3% and the rest (26.5%) were active adults. Residents of commune V accounted for 92.6% of cases and the others (7.4%) came from Kati; of commune IV and commune VI.

esophageal cases. $p=0.0455$.

- 6) In the other cases there were no statistical significance differences. $p > 0.05$.

4.3. Clinical Aspects

The main reasons for medical consultation were otalgia 33.8% for otological locations; nasal obstruction 14.6% for nasals and dyspnea 4.4% for pharyngolaryngeal and bronchial locations. Penetration syndrome was noted on interrogation for bronchial foreign bodies. Dysphagia and vomiting have been the main symptom of foreign objects in the esophagus. The circumstances of occurrence were gambling in 57.4%; the meal and accidentally for the rest of the cases (42.6%). There was no specific pathological history reported. The consultation time varied from 24 hours to one week in 47.1% of cases following the accident. In 22%, the consultation took place within 24 hours of the accident. The rest (30.9%) took more than a week. The different locations are shown in Tables 1 and 2. The localization was otological (58.83%), nasal (32.35%), bronchial (2.94%), and oesophageal (2.94%). The nature of the foreign bodies is recorded in Table 3. It was inorganic in 52.94%, food organic in 13.23%, plant organic in 23.53%, and insects in 10.3%.

Table 3. Distribution according to the nature of the foreign bodies.

Nature	Effective	Percentage (%)
Cotton	13	19.1
Sponge	08	11.8
Pebble	09	13.2
Insect	07	10.3
Pearl	07	10.3
Food	09	13.2
rubber	05	7.4
Piece of chalk	03	4.4
Piece of wood	02	2.9
piece of money	02	2.9
piece of paper	01	1.5
lump of coal	01	1.5
button cell battery	01	1.5
Total	68	100

4.4. Therapeutics Aspects

Ear washing was performed in 57.4% of the cases; chairside forceps extraction in 36.8%. Esophagoscopy and bronchoscopy each 2.9% under general anesthesia.

5. Discussion

The limits of this work are follow:

- 1) The work environment was characterized by the lack of adequate equipment and infrastructure for ENT. All of the political choices are focused primarily on gynecology and obstetrics. The staff of the unit consists of a Doctor with four medical assistants. This state of affairs often obliges us to refer certain patients to structures that are better equipped but also well equipped with human resources for optimal care needs. Due to the insufficiency or absence of data on some

patients, they were not included in this work. Further work on the referred cases can give a precise estimate of all cases in terms of frequency in our structure.

- 2) The country's under-medicalization, linked in part to a lack of infrastructure and a certain degree of obscurantism of the families, contributes to a long consultation period. In some cases, treatment is initially provided by traditional therapists or often by health workers who are ill-informed on the issue. The risks of complications, which are often fatal, even before patients arrive at an appropriate health facility are real. Further study from this angle could be of interest. Information, education and communication with parents, patients and even with non-ENT health personnel is essential.
- 3) The size of the participants was small (68) leading weaker statistical significance. A longer study period (between 5 or 10 years) could help to have a larger participant size.

5.1. Frequency

Foreign bodies in ENT represented 1.47% of all medical consultations in the ENT unit of the CSREF CV. This result is significantly lower as compared to that of a previous study in the same unit conducted in 2017. That 2017 study found that foreign bodies represented 4% of ENT consultations [7]. Previous 2017 study is also in agreement with study conducted by Njiffou [8] where ENT foreign bodies represented 2.58% of consultations in the ENT department at the Laquinitine hospital in Douala (Cameroon). Ouoba found that foreign bodies occupied a notable place in emergencies, ie 33.07% at Ouagadougou hospital [9].

5.2. Sociodemographic Aspects

The majority of patients were 41.2% preschool children, followed by 32.3% school and university students. These accidents occur in the vast majority of cases in children under 6 years like in our study where we found that 42.6% were under 5 years old. The youngest patient was 10 months old and 72.05% of patients were under 15 years old [10].

The male sex was predominant (52.9%) with a sex ratio of 1.2. Sex ratio from most authors was similar; 1.8 from Kacouchia [3] and 1.5 from Khaoula [1]. This could be explained by the fact that little boys, in general, have a more developed instinct for discovery and are more rowdy than little girls of the same age. Indeed, it is well known that childhood is a period of exploration of oneself and of one's environment. And that the little boy is more turbulent and reckless than the little girl [11].

5.3. Clinical Aspects

The foreign body is generally accidental occurring during play or meals and the nature of the object dependent on those placed at the disposal of the child in his immediate environment [12]. It usually occurs in people with normal development. It can be favored by a particular ground:

mental retardation, trisomy or any other psychomotor disability [1]. In our study, 57.4% occurred during gambling and we did not record any particular pathological history. This result is close to that of Diallo *et al.* in Guinea, which found that in the majority of cases (54.17%), foreign bodies are introduced during games [2].

In our study, more than half of the cases (58.9%), the foreign bodies were located in the external auditory canal distributed between 25 boys and 15 girls, with an average age of 20 years and extremes of 1 year and 76 years old; results comparable to certain publications where atrial localization predominated at 52.23% [13]; 57.8% [14]; and 64.7% [2]. Other studies have found other results. In this case those carried out by Khaoula [1] and Kharoubi [5] who found that esophageal foreign bodies represented the highest incidence at 47.53% and 51.02% respectively. We found 22 cases of nasal foreign bodies representing 32.4% of cases divided into 7 boys and 15 girls. Their average age was 4 +/- 2.5 years with extremes ranging from 18 months to 14 years. The predominance of atrial and nasal foreign bodies is not surprising, as young children are by nature curious and enjoy exploring the openings of their bodies, especially the nose and ears [15].

Almost half of the patients (47.1%) were seen in consultation during the first week beyond the 24th hour following the notion of the foreign body. Early consultations in less than 24 hours only accounted for 22%. The predominance (78%) of delayed consultations could be explained by the obscurantism of the parents and often by a certain degree of inattention from the parents. A study of parental attitudes, behavior and knowledge of foreign bodies could support this claim. The most common occurrence of the accident occurred during play. In the absence of improper handling during a failed extraction attempt, atrial seat foreign bodies are not very symptomatic [12]. But over time, for nasal foreign bodies, unilateral purulent rhinorrhea may develop with a foul odor and epistaxis [15]. The nature of the foreign bodies was variable and diverse. In our study, we noticed a predominance of inorganic foreign bodies as in Tall's study [10]. A case of button cell battery was observed at the nasal level. Button cells are a special case, particularly dangerous, and the cause of serious lesions (mucosal ulcerations are almost systematic) [16]. More and more devices for daily use, within reach of children in homes, use this type of battery, thus increasing the risk of ingestion [4]. Esophageal, pharyngeal and bronchial foreign bodies; together with nasal foreign bodies constitute the foreign bodies of the aero-digestive tract. Two cases were observed for each without complications. The diagnosis of foreign bodies can sometimes be easy [12]. Symptoms and diagnostic methods depend on the site [11]. Indeed, those of the nose and pharynx can be revealed by careful clinical examination, as some authors attest [12]. The penetration syndrome directs towards a foreign body of the laryngotracheobronchial pathway. In some cases, radiography is important in the diagnostic approach. However, the absence of radiological signs should not reject the diagnosis of foreign bodies [3]. Dysphagia and

hypersialorrhea can direct to foreign bodies in the esophagus or pharynx [11, 17]. In the present study, the x-ray diagnosed foreign bodies in the esophagus and bronchi.

5.4. Therapeutic Aspects

The extraction was carried out by natural means according to the principle of Chevalier Jackson, who said in 1951: "Any foreign body of the digestive or airways which has entered through the digestive or airways must be extracted by the same routes provided that 'it did not migrate through the perforated wall of these pathways'" [18, 19]. Exceptions to this rule had to be transferred so were not included in this study. Extraction is often done without or under local anesthesia by the introduction routes, under visual guidance with a Clar mirror, using a microscope or rigid or flexible endoscopy. The use of specific forceps for extraction is the most widely used technique. The use of general anesthesia for the extraction of foreign bodies in the literature varies between 8.6% and 30% of cases [2]. In the present study, general anesthesia was only used in esophageal and bronchial foreign bodies removal representing thus 4 cases (5.88%). Complications from foreign bodies in the ENT sphere can be serious, such as obstruction of the upper respiratory tract leading to suffocation, visceral perforations and serious infections (mediastinitis, pneumonia) [2, 20]. We have not recorded any cases, but in the literature its rate can reach 22% [1, 2].

6. Conclusion

Foreign bodies in ENT, represent a pathology of importance because of its frequency and its potential severity. Auricular and nasal locations are more frequent. These accidents occur in the vast majority of cases in little boys. It seems essential to us to consider this problem of foreign bodies from the angle of prevention by a real education of parents on the choice of toys and objects made available to children. The enhancement of the technical platform of peripheral health structures is necessary to relieve congestion in hospitals allowing prompt treatment and care.

Declaration of Interests

The authors declare that they have no conflicts of interest for this case study.
